Problem Statement

https://datatracker.ietf.org/doc/draft-mozley-aidiscovery/

"Several alternative approaches to agent discovery have been proposed, including centralized registries, blockchain-based naming systems, locahost gateways, and proprietary service directories. While these models may offer novel features, they introduce significant architectural, operational, and most importantly **governance** challenges. Centralized registries concentrate control and introduce single points of failure, limiting resilience and scalability."

Internal

Functional Problems

- Who discovers (an entity)
- Who is discovered (another entity or a class of entities)
- What information is being discovered?
- Who is responsible for this vs anonymous
- Type (e.g., IETF, Microsoft,...)
- What it does (functionality)

- How much of this function can it do
- How do I communicate with the entity (and security for communications)
- Who made the registration (trust or no-trust authentication)
- Discovered Information may be further categorised as:

- Mandatory or Optional
- Static, Mainly Static, or Dynamic
- Extensible by vendor/implementation, through further standardisation, or not at all

Internal

Out of Scope

- How do I register my entity (with option for attestation)
- Trust
- Responsibility
- Capability and Negotiation
- Tasks Management
- Agent-to-agent communications

Internal
